Importing Relational Data with Sqoop

Prof. Hyuk-Yoon Kwon

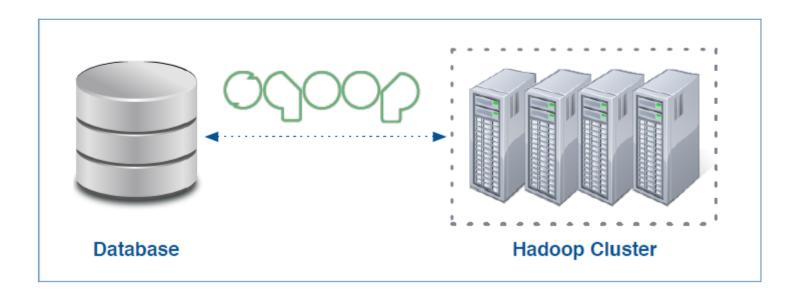

Importing Relational Data with Apache Sqoop

In this chapter you will learn

- How to import tables from an RDBMS into your Hadoop cluster
- How to change the delimiter and file format of imported tables
- How to control which columns and rows are imported
- What techniques you can use to improve Sqoop's performance
- How the next-generation version of Sqoop compares to the original

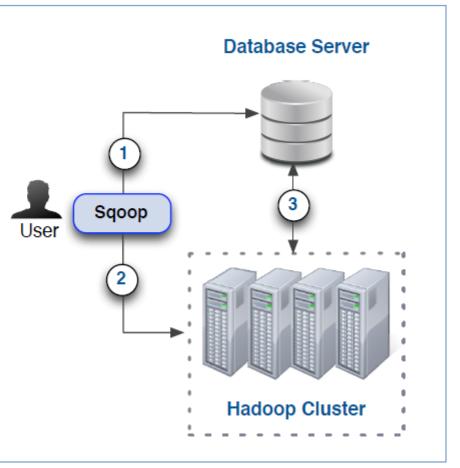

What is Apache Sqoop?

- Open source Apache project originally developed by Cloudera
 - The name is a contraction of "SQL-to-Hadoop"
- Sqoop exchanges data between a database and HDFS
 - Can import all tables, a single table, or a partial table into HDFS
 - Data can be imported a variety of formats
 - Sqoop can also export data from HDFS to a database

How Does Sqoop Work?

- Sqoop is a client-side application that imports data using Hadoop MapReduce
- A basic import involves three steps orchestrated by Sqoop
 - Examine table details
 - Create and submit job to cluster
 - Fetch records from table and write this data to HDFS

Basic Syntax

- Sqoop is a command-line utility with several subcommands, called tools
 - There are tools for import, export, listing database contents, and more
 - Run **sqoop help** to see a list of all tools
 - Run **sqoop help tool-name** for help on using a specific tool
- Basic syntax of a Sqoop invocation

```
$ sqoop tool-name [tool-options]
```

This command will list all tables in the loudacre database in MySQL

```
$ sqoop list-tables \
    --connect jdbc:mysql://dbhost/loudacre \
    --username dbuser \
    --password pw
```

Overview of the Import Process

- Imports are performed using Hadoop MapReduce jobs
- Sqoop begins by examining the table to be imported
 - Determines the primary key, if possible
 - Runs a boundary query to see how many records will be imported
 - Divides result of boundary query by the number of tasks (mappers)
 - Uses this to configure tasks so that they will have equal loads
- Sqoop also generates a Java source file for each table being imported
 - It compiles and uses this during the import process
 - The file remains after import, but can be safely deleted

Importing an Entire Database with Sqoop

- The import-all-tables tool imports an entire database
 - Stored as comma-delimited files
 - Default base location is your HDFS home directory
 - Data will be in subdirectories corresponding to name of each table

```
$ sqoop import-all-tables \
  --connect jdbc:mysql://dbhost/loudacre \
  --username dbuser --password pw
```

Use the --warehouse-dir option to specify a different base directory

```
$ sqoop import-all-tables \
   --connect jdbc:mysql://dbhost/loudacre \
   --username dbuser --password pw \
   --warehouse-dir /loudacre
```

Importing a Single Table with Sqoop

- The import tool imports a single table
- This example imports the accounts table
 - It stores the data in HDFS as comma-delimited fields

```
$ sqoop import --table accounts \
    --connect jdbc:mysql://dbhost/loudacre \
    --username dbuser --password pw
```

This variation writes tab-delimited fields instead

```
$ sqoop import --table accounts \
    --connect jdbc:mysql://dbhost/loudacre \
    --username dbuser --password pw \
    --fields-terminated-by "\t"
```

Practice: Import Data

- 1. List the tables in the **loudacre** database
- 2. Use Sqoop to import the accounts table in the loudacre database and save it in HDFS under /loudacre
- 3. List the contents of the **accounts** directory under /loudacre
- 4. Use HDFS tail command to view the last part of the file for each of the MapReduce partition files
- 5. The first six digits in the output are the **account ID**. Take note of highest **account ID** because you will use it in the next step

Incremental Imports (1)

- What if records have changed since last import?
 - Could re-import all records, but this is inefficient
- Sqoop's incremental lastmodified mode imports new and modified records
 - Based on a timestamp in a specified column
 - You must ensure timestamps are updated when records are added or changed in the database

```
$ sqoop import --table invoices \
    --connect jdbc:mysql://dbhost/loudacre \
    --username dbuser --password pw \
    --incremental lastmodified \
    --check-column mod_dt \
    --last-value '2015-09-30 16:00:00'
```

Incremental Imports (2)

- Or use Sqoop's incremental append mode to import only new records
 - Based on value of last record in specified column

```
$ sqoop import --table invoices \
    --connect jdbc:mysql://dbhost/loudacre \
    --username dbuser --password pw \
    --incremental append \
    --check-column id \
    --last-value 9478306
```

Practice: Import Incremental Update

- Run the add_new_accounts.py script to add the latest accounts to MySQL
- 2. Incrementally import and append the newly added accounts to the accounts directory. Use Sqoop to import on the last value on the acct_num column largest account ID
- 3. List the contents of the accounts directory to verify the Sqoop import.
- 4. You should see three new files. Use Hadoop's cat command to view the entire contents of these files

Exporting Data from Hadoop to RDBMS with Sqoop

- Sqoop's import tool pulls records from an RDBMS into HDFS
- It is sometimes necessary to push data in HDFS back to an RDBMS
 - Good solution when you must do batch processing on large data sets
 - Export results to a relational database for access by other systems
- Sqoop supports this via the export tool
 - The RDBMS table must already exist prior to export

```
$ sqoop export \
    --connect jdbc:mysql://dbhost/loudacre \
    --username dbuser --password pw \
    --export-dir /loudacre/recommender_output \
    --update-mode allowinsert \
    --table product_recommendations
```

Importing Partial Tables with Sqoop

Import only specified columns from accounts table

```
$ sqoop import --table accounts \
    --connect jdbc:mysql://dbhost/loudacre \
    --username dbuser --password pw \
    --columns "id, first_name, last_name, state"
```

Import only matching rows from accounts table

```
$ sqoop import --table accounts \
    --connect jdbc:mysql://dbhost/loudacre \
    --username dbuser --password pw \
    --where "state='CA'"
```

Using a Free-Form Query

- You can also import the results of a query, rather than a single table
- Supply a complete SQL query using the --query option
 - You must add the *literal* WHERE \$CONDITIONS token
 - -Use --split-by to identify field used to divide work among mappers
 - -The --target-dir option is required for free-form queries

```
$ sqoop import \
    --connect jdbc:mysql://dbhost/loudacre \
    --username dbuser --password pw \
    --target-dir /data/loudacre/payable \
    --split-by accounts.id \
    --query 'SELECT accounts.id, first_name,
last_name, bill_amount FROM accounts JOIN invoices ON
(accounts.id = invoices.cust_id) WHERE $CONDITIONS'
```

Using a Free-Form Query with WHERE Criteria

- The --where option is ignored in a free-form query
 - You must specify your criteria using AND following the WHERE clause

```
$ sqoop import \
    --connect jdbc:mysql://dbhost/loudacre \
    --username dbuser --password pw \
    --target-dir /data/loudacre/payable \
    --split-by accounts.id \
    --query 'SELECT accounts.id, first_name,
last_name, bill_amount FROM accounts JOIN invoices ON
  (accounts.id = invoices.cust_id) WHERE $CONDITIONS AND
bill_amount >= 40'
```

Options for Database Connectivity

Generic (JDBC)

- Compatible with nearly any database
- Overhead imposed by JDBC can limit performance

Direct Mode

- Can improve performance through use of database-specific utilities
- Currently supports MySQL and Postgres (use --direct option)
- Not all Sqoop features are available in direct mode

Controlling Parallelism

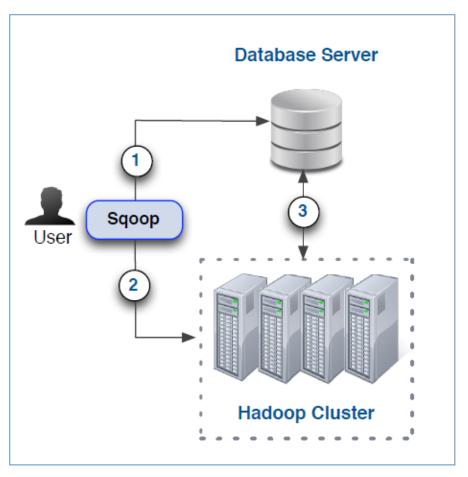

- By default, Sqoop typically imports data using four parallel tasks (called mappers)
 - Increasing the number of tasks might improve import speed
 - Caution: Each task adds load to your database server
- You can influence the number of tasks using the -m option
 - Sqoop views this only as a hint and might not honor it

```
$ sqoop import --table accounts \
    --connect jdbc:mysql://dbhost/loudacre \
    --username dbuser --password pw \
    -m 8
```

- Sqoop assumes all tables have an evenly-distributed numeric primary key
 - Sqoop uses this column to divide work among the tasks
 - You can use a different column with the --split-by option

Limitations of Sqoop

- Sqoop is stable and has been used successfully in production for years
- However, its client-side architecture does impose some limitations
 - Requires connectivity to RDBMS from the client (client must have JDBC drivers installed)
 - Requires connectivity to cluster from the client
 - Requires user to specify RDBMS username and password
 - Difficult to integrate a CLI within external applications
- Also tightly coupled to JDBC semantics
 - A problem for NoSQL databases

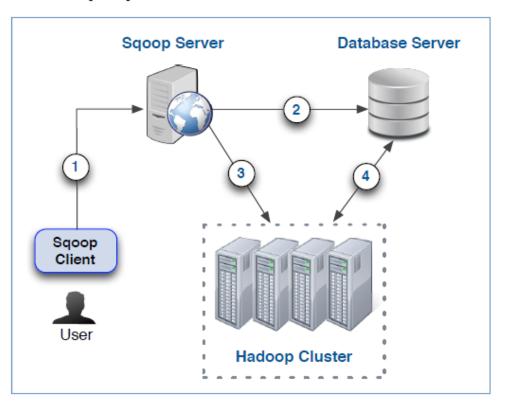

Sqoop 2 Architecture

Sqoop 2 is the next-generation version of Sqoop

- Client-server design addresses limitations described earlier
- API changes also simplify development of other Sqoop connectors

Client requires connectivity only to the Sqoop server

- DB connections are configured on the server by a system administrator
- End users no longer need to possess database credentials
- Centralized audit trail
- Better resource management
- Sqoop server is accessible via
 CLI, REST API, and Web UI

Essential Points

- Sqoop exchanges data between a database and the Hadoop cluster
 - Provides subcommands (tools) for importing, exporting, and more
- Tables are imported using MapReduce jobs
 - These are written as comma-delimited text by default
 - You can specify alternate delimiters or file formats
 - Uncompressed by default, but you can specify a codec to use
- Sqoop provides many options to control imports
 - You can select only certain columns or limit rows
 - Supports using joins in free-form queries
- Sqoop 2 is the next-generation version of Sqoop
 - Client-server design improves administration and resource management
